This group of compounds is closely related to the pyrimidines and pyridines, and is commonly called the beta-cyanurates. Many of these compounds contain a cyano group, a pyrimidine ring, and a water group which is bonded to the cyano group, with the remainder of the molecule being bonded to an amine group. The beta-cyanurates are chemical precursors to heterocyclic compounds such as hydantoins and ureas, and thus have been used extensively in the industrial production of such chemicals. However, it is difficult to maintain the hydration of the cyano group in the beta-cyanurates, making these compounds difficult to hydrolyze to their corresponding hydantoins and urea. In addition, the need for substantial quantities of cyanide and a long reaction time to achieve conversion to the heterocyclic compounds limits the utility of the beta-cyanurates as an intermediate. It is known that some cyanurates are susceptible to decomposition by strong acid. U.S. Pat. No. 3,275,679 describes the reaction of a hydrocarbon-saturated di-sodium salt of cyanuric acid, such as Na<sub>2</sub>C<sub>3</sub>H<sub>3</sub>O<sub>3</sub>, with concentrated HCl to produce 1-(2,2,2-trichloro-1-ethoxyethyl)-2,2-dihydro-5-cyano-1,
