Rhode Island with family and friends, and perfect for a New England holiday. In electrical connectors, an electrical conductor or other conductors have often been soldered to a conductor-carrying metal support member such as a printed circuit board or a flex circuit. The conductors are individually soldered to the support member by clamping each conductor between the clamping surface of the tool and the edge of the support member, and by heating the clamped assembly in a furnace or by the application of an electrical current to the clamped assembly, the conductors and the support member melt together and are fused. After the soldering step is completed, the conductors are ready for use, without further steps. A wide variety of clamping tools are known to be used for such soldering operations. There has been a constant need to reduce the size of the tooling necessary to carry out such soldering operations. Reducing the size of such tools has resulted in substantial reductions in the cost of the tool. This need has been particularly evident in recent years, since the demand for mass-produced electronic devices, such as computers, communications equipment, and the like, has grown considerably. There has been a demand for even smaller tools, and this demand has resulted in a requirement that the size of the tools be reduced to the point

With an in memory database, the database engine is the fastest component that most application servers have. To maximize performance, the SQL engine is pre-compiled. The Java code generated by the Java compiler is also optimized with some meta information. HSQL is a small, fast engine with both in memory and disk based tables.
