This Guide provides guidelines for establishing a regular distribution of software updates in a Cisco packet-switched router network. In a basic implementation, the method described here is commonly used

to distribute any piece of software, such as the Cisco IOS or Cisco IOS XE software, or Cisco IOS ASDM bundles. Gently releasing software packages to about 500 devices in the network at a time is good testing ground for software distribution. Software updates may be classified into software images, software bundles, and software bundles with helper data. This section describes how to automate the distribution of software updates in a Cisco packet-switched router network. Step 1 Establish a Configuration Change Management Plan Step 2 Install Software Updates Updating software in a Cisco packet-switched router network takes the form of software images, software bundles, and software bundles with helper data. Software images typically contain the full Cisco IOS or Cisco IOS XE software image. Helper data (also known as prerequisites or prerequisite packages) are additional software packages that are required before the main software bundle is installed. Some software bundles contain these prerequisites as well as the main software package. In this case, the bundle is considered an update to the software bundle that was previously installed. Software bundles with helper data contain all of the prerequisites and the main software package. Software images are typically in the form of an image file and optionally also contains a per-device software configuration file (such as an ipconfig file or a conng file). Software bundles are typically in the form of a package file, an archive file, or a tarball. Bundles with helper data are typically in the form of a package file, an archive file, or a tarball. Requirements for installing new software on a router device in a Cisco packet-switched router network include the following: The software image or bundle must be contained in a sufficiently sized file that is transferable over the network using a technique such as TFTP (Trivial File Transfer Protocol). The network has at least one server or network address translator (NAT) that can perform a consistent file transfer. If the server must run a version of the software that is different from that of the device running the software, then the server must support a configuration file format that is able to store differences between host and server software packages. The server must support FTP (File Transfer Protocol). For
