Players compete in shooting games of various types, including skeet shooting, pistol shooting, free-throw shooting, and various other types. In skeet shooting, a person (known as a gunner) shoots a clay disk toward a goal. The clay disk is often a rounded ball that resembles a ceramic or plastic ball. The shot is often characterized by the distance, by the type of ball, and by how the ball travels to the goal. Gunners may shoot from distances of 3 yards or more and may shoot at a variety of different angles and different directions. In skeet shooting, a majority of the shots land within approximately one foot of the target, with an average of approximately 84% of the shots landing within an area of approximately six inches. There are various skeet shooting systems in which the gunner continues to shoot until a minimum number of targets are hit. To score, each clay disk has a number of bumps or nubs. When the clay disk hits the target, the nubs break, causing an identifiable sonic sound. Gunners are judged by how well they line up the shot with the nubs. One problem with skeet shooting is that the shooter must have some physical control of the firearm. This is because the firearm must be physically moved and then the clay disks must be handled when the shooter shoots. As a result, skeet shooting is largely a stationary activity. It is not a sport that provides for the enjoyment of physical activity or the opportunity to share a unique hobby with friends or family. The present invention relates to a keyless tapping system and, more particularly, to such a system in which a transmitter coil is inductively coupled with a receiver coil to form a radio frequency induction loop. An inductance is caused by a pair of receiver coil conductors to form a capacitor. The capacitor and transmitter coil act as an antenna in this commonly used system. The capacitor forms part of an amplifier that further includes a pre-amplifier and a switching means. A step-up transformer is located adjacent the amplifier to amplify a signal received by the transmitter coil. The signal is substantially reduced in magnitude and, subsequently, amplified by the amplifier. The amplified signal is transmitted from the amplifier to a receiver which includes a comparator. The output of the comparator is received by a control circuit that includes a microprocessor. The control circuit compresses the received signal using a plurality of threshold levels. A display such as an LED, LCD or some other conventional method is then used to display the result.
